## New Claims

- 1. Data link layer device for a serial communication bus, in particular IEEE1394 bus, comprising an interface (35) to 5 a physical layer unit (20) and an interface to at least one host processor supporting the higher layers of the OSI/ISO data communication reference model, characterized in that, the data link layer device further comprises means (31b) for checking whether a cycle master capable of transmitting a cycle start packet determining minimum 10 start times for isochronous and asynchronous data transmissions over the serial communication bus exists in the network and if not activating configuration means (38) that enable the generation of asynchronous 15 transmission requests without waiting for a cycle start packet and an isochronous data transfer in order to support a no cycle master transfer mode.
- 2. Data link layer device according to claim 3 wherein the 20 means for checking whether a cycle master exists in the network comprise a memory (37) storing the selfidentification packets from all the nodes in the network and evaluating means for checking whether in one of the self-identification packets an entry is found that 25 indicated that the corresponding node is contender for an isochronous resource manager (42).
- 3. Data link layer device according to claim 3, wherein the means for checking whether a cycle master exists in the 30 network comprise a first counter (31a) counting clock pulses of a reference clock, the counter generating a cycle synchronization event each time after a predetermined counting interval, and comprising a second counter that is incremented each time that no cycle start

2

packet has been received in succession to a cycle synchronization event, thereby activating said configuration means if the second counter reaches a predetermined value.
